Pods vs Containers	https://medium.com/google-cloud/kubernetes-101-pods-nodes-containers-and-clusters-c1509e409e16

Deployment	<pre> # replication controller #replication set # deployment https://www.bmc.com/blogs/kubernetes-deployment/ kubectl create -f deployment/helloworld.yml kubectl get deployments or kubectl get deploy kubectl get service,pvc,deployment,pods kubectl get all grep hello-world kubectl get rs or kubectl get replicaset kubectl rollout status deployment/helloworld-deployment kubectl rollout history deployment kubectl set image deployment/helloworld-deployment k8s- demo=wardviaene/k8s-demo:2 kubectl rollout status deployment/helloworld-deployment curl http://192.168.99.103:30353 kubectl rollout history deployment kubectl scale --replicas=4 deployment helloworld-deployment kubectl rollout undo deployment/helloworld-deployment kubectl rollout undo deployment/helloworld-deployment --to- revision=3 kubectl delete deployment hello-world ReplicaSet is the next-generation Replication Controller. we recommend using Deployments instead of directly using ReplicaSets, unless you require custom update orchestration or don't require updates at all.This actually means that you may never need to manipulate ReplicaSet objects: use a Deployment instead, and define your application in the spec section. type:deployment vs type:pod Both Pod and Deployment are full-fledged objects in the Kubernetes API. Deployment manages creating Pods by means of ReplicaSets. kubectl edit deployment/helloworld-deployment spec: progressDeadlineSeconds: 600 replicas: 4 revisionHistoryLimit: 10 </pre>
Pod	<pre> kubectl get pods --show-labels kubectl describe pod myPodName -n myNameSpace </pre>

Service

```
kubectl expose deployment helloworld-deployment --  
type=NodePort --name=example-service
```

This is equivalent to **kubectl create -f** the following yaml:

```
apiVersion: v1  
kind: Service  
metadata:  
  name: example-service  
spec:  
  ports:  
    - port: 31001  
      nodePort: 31001  
      targetPort: nodejs-port  
      protocol: TCP  
  selector:  
    app: helloworld  
  type: NodePort
```

Kubectl get service

kubectl describe service example-service

minikube service example-service --url

curl <http://192.168.99.103:30353>

A Kubernetes Service is an abstraction which defines a logical set of Pods running somewhere in your cluster, that all provide the same functionality. When created, each Service is assigned a unique IP address (also called clusterIP). This address is tied to the lifespan of the Service, and will not change while the Service is alive. Pods can be configured to talk to the Service, and know that communication to the Service will be automatically load-balanced out to some pod that is a member of the Service.

ClusterIP: makes the service only reachable from within the cluster. This is the default ServiceType.

NodePort : Kubernetes will allocate a specific port on each Node to that service, and any request to your cluster on that port gets forwarded to the service.

Limitation: have to take care of load balancing so that you leverage the power of your pod replicas. if you want to manage load balancing systems manually and set up port mappings yourself.

LoadBalancer : There needs to be some external load balancer functionality in the cluster, typically implemented by a cloud provider.

This is typically heavily dependent on the cloud provider. Every

	Kubectl delete svc example-service
LivenessProbe RedinessProbe	<p>liveness probes to know when to restart a Container.</p> <p>readiness probes to know when a Container is ready to start accepting traffic.</p>

Secret	<p>kubectl create secret generic apikey --from-literal=API_KEY=123-456</p> <p>kubectl get secret</p>

Before developers can start using the storage, administrators need to provision persistent volumes. Unlike volumes, persistent volumes are not associated with any specific pod or containers when they are created. They are pre-provisioned storage resources that can be used by developers during the creation of a pod. Once persistence volumes (PersistentVolume) are provisioned by administrators, developers create a claim (PersistentVolumeClaim) to start consuming the storage resources exposed as persistent volumes.

Volume

When running multiple containers together in a Pod it is often necessary to share files between those containers; volumes are used for this purpose.

PERSISTENT VOLUME

A PersistentVolume (PV) is a piece of storage in the cluster. It is a resource just like a node is a cluster resource.

PVs are volume plugins like volumes but have a lifecycle independent of any individual pod that uses the PV.

Volumes will be deleted when Pods are deleted, while Persistent Volumes are different entities, completely decoupled from the Pod. PVs are managed by a different set of APIs \ kubectl than Pods and have their own Lifecycle.

PERSISTENT VOLUME CLAIMS

A PersistentVolumeClaim (PVC) is a request for storage. It is similar to a pod. While Pods consume node resources, PVCs consume Persistent Volume resources. Pods can request specific levels of resources (CPU and Memory). Claims can request specific size and access modes (e.g., can be mounted once read/write or read-only).

Volume	<p>minikube ssh</p> <p>Sql https://kubernetes.io/docs/tasks/run-application/run-single-instance-stateful-application/ https://dev.mysql.com/doc/mysql-getting-started/en/</p> <p>if you get this error Can't create database 'database'. (errno: 13) http://www.webhostingtalk.com/showthread.php?t=361700</p> <p>change to the directory above the mysql dir, probably var/lib/ # cd /var/lib</p> <p>Check the owner and group with # ls -ld mysql</p> <p># chown -R mysql:mysql mysql</p> <p>Nginx https://kubernetes.io/docs/tasks/configure-pod-container/configure-persistent-volume-storage/</p> <p>Wordpress https://kubernetes.io/docs/tutorials/stateful-application/mysql-wordpress-persistent-volume/ https://dotlayer.com/how-to-run-wordpress-in-a-kubernetes-cluster/</p>

Ingress	<p>it sits in front of multiple services and act as a “smart router” or entrypoint into your cluster. Ingress Controllers can technically be any system capable of reverse proxying, but the most common is Nginx. It is a completely independent resource to your service. You declare, create and destroy it separately to your services.</p> <p>https://matthewpalmer.net/kubernetes-app-developer/articles/kubernetes-ingress-guide-nginx-example.html https://velotio.com/blog/2017/7/5/http-load-balancing-in-kubernetes-with-ingress https://medium.com/@awkwardferny/getting-started-with-kubernetes-ingress-nginx-on-minikube-d75e58f52b6c</p> <p>minikube addons enable ingress # wait a min for the pod to be up and running \$ kubectl get pods -n kube-system grep nginx-ingress-controller</p> <p>Kubernetes ingress resource lacks of quite important functionality, mainly mutual TLS for incoming connections (currently only support server certificates), supporting SNI (releated with the previous one), non-HTTP traffic load balance, and if you want to use Istio features like Traffic splitting, fault injection, mirroring, header match, etc are not available between ingress controller and backend... I was looking for for an implementation like this, let see if "gateway" finally works and performance is as good as ingress controller.</p> <p>Case study: https://engineering.shopify.com/blogs/engineering/iterating-towards-more-stable-ingress</p>

Service discovery	<p>Kubernetes DNS schedules a DNS Pod and Service on the cluster, and configures the kubelets to tell individual containers to use the DNS Service's IP to resolve DNS names.</p> <p>kubectl get services kube-dns --namespace=kube-system</p> <p>https://docs.microsoft.com/en-us/azure/aks/kubernetes-walkthrough</p> <p>You can expose your application via a ClusterIP service. ClusterIP is the default ServiceType and it creates a single IP address that can be used to access its Pods which can only be accessed from inside the cluster. If KubeDNS is enabled it will also get a series of DNS records assigned to it include an A record to match its IP. This is very useful for exposing microservices running inside the same Kubernetes cluster to each other.</p> <pre>kubectl run -i --tty busybox --image=busybox --restart=Never --sh #nslookup azure-vote-back</pre> <pre>Kubectl get pods kubectl exec -it azure-vote-front-fc749d98c-h642z -- /bin/bash #ping azure-vote-back</pre> <p>Note: to speak between 2 containers in the same pod you don't need dns. Use localhost:port</p>
